One of the major problems in the polyurethane industry is the production of a polyurethane which is stable to moisture. In many instances, the most stable polyurethanes are cast polyurethanes which are generally made as mixtures of prepolymers, generally polyether polyols, and polyisocyanate compounds such as toluene diisocyanate. These cast polyurethanes are, however, generally too brittle to be useful. To alleviate the problem of brittleness in cast polyurethanes, it has heretofore been proposed to use polyether polyols having terminal silyl groups. See, for example, U.S. Pat. Nos. 3,770,617, 3,917,676, 4,071,420, 4,156,061 and 4,142,003. In general, the silyl-terminated polyethers disclosed in these patents are mixtures of compounds containing terminal silyl groups and compounds containing terminal polyoxyalkylene groups and at least two isocyanate-reactive hydrogen atoms. While the described materials are useful in that they provide a cast polyurethane having improved flexibility, the materials are not always totally satisfactory. In some instances, the presence of a substantial amount of the compounds with terminal polyoxyalkylene groups causes the polyurethane, when reacted with a polyisocyanate to form the polyurethane composition, to have a substantially lower than desirable tensile strength. Additionally, some of these materials are very difficult to process. For example, a solid polymer which contains 10 to 20% by weight of polyoxyalkylene-terminated material is substantially insoluble in general purpose solvents. It has now been found that a polyurethane is provided which is stable to moisture and has a desirable tensile strength when prepared from polyether polyols having terminal bis-trichlorosiloxy groups.Q: Creating a user login and registration program in c using ctypes I'm making an imgui based login/registration program in c using ctypes.
